A grammar is in **Chomsky normal form** if all of its rule have one of the following forms:

- 1. $A \to BC$, where B, C are not the start variable.
- 2. $A \rightarrow a$, where a is any terminal.
- 3. $S \rightarrow \epsilon$.

Theorem Any context free grammar is equivalent to a grammar in Chomsky normal form.

1. Let G be a grammar in Chomsky normal form. Prove that if $w \in \Sigma^*$ can be generated by G and |w| = n, then it takes exactly 2n - 1 steps to generate w using G.

2. Consider the following grammar which is in Chomsky normal form.

$$\begin{array}{ccccc} S \rightarrow AR & S \rightarrow a & S \rightarrow \epsilon \\ R \rightarrow BT & R \rightarrow b & A \rightarrow a & B \rightarrow b \\ T \rightarrow CD & T \rightarrow c & C \rightarrow c & D \rightarrow d \end{array}$$

Fill in the following table by listing all variables from $V = \{S, A, B, C, D, R, T\}$ that can generate each string. For example, c can be generated by both C and T.

a:	ab:	abc:	abcd:
b:	bc:	bcd:	
c: C, T	cd:		
d:			

3. Let $w \in \Sigma^*$ with |w| = n. How many (contiguous) substrings can w have? Hint: think about the number of substrings of length 1, then length 2, etc. It might help to think about a simple example like $w = \mathtt{abcde}$.

4. The following algorithm uses dynamic programming to decided whether a string w can be generated by a grammar in Chomsky normal form. The idea is to create a table to record variables that can generate substrings of w and use it to decide if w can be generated.

```
# Build a table to track which substrings can be generated.
for substring of w:
  if length(substring) == 1:
    for "A -> a" in rules:
      if substring == "a":
        add A to Table[substring]
  else:
    for k from 0 to length(substring):
      left_substring = substring[0:k]
      right_substring = substring[k+1:end]
      for "A -> BC" in rules:
        if B in Table[left_substring] and C in Table[right_substring]:
          add A to Table[substring]
# Then check if w can be generated.
if Table[w] includes "S":
  return True
else:
  return False
```

What is the running time (in big-O notation) for this algorithm to decide if a string w with length n can be generated by a grammar in Chomsky normal form?
